## Functional cell assemblies, or engrams

# Excitability

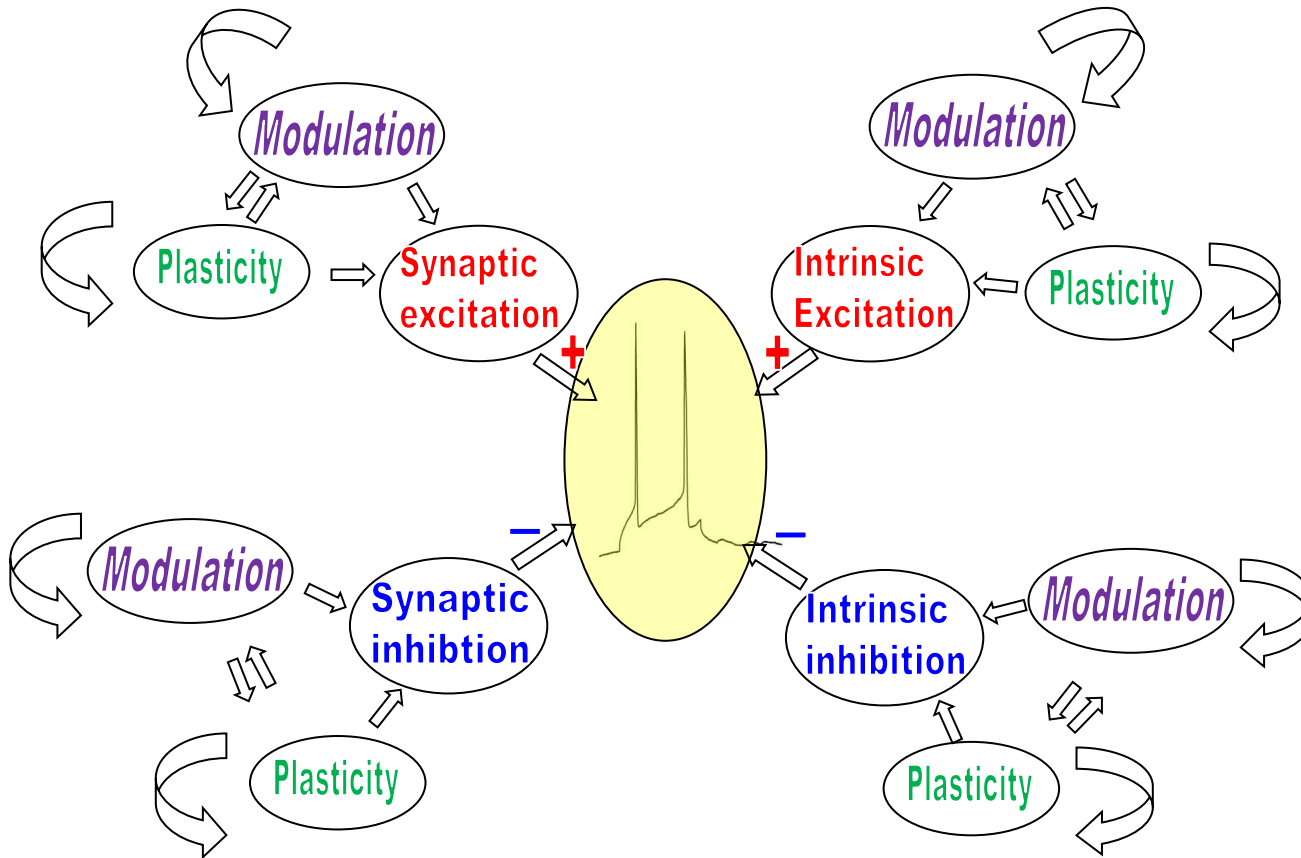

- the likelihood of evoking action potentials

# Synaptic and Intrinsic Excitability

# Modulation and Plasticity of Excitability

**Plasticity** – based on neuronal activity - aims to create / erase engrams

**Modulation** – based on release of modulatory neurotransmitters –  
modulate the accessibility of engrams

# Electrophysiology – different levels of reductionism

Single protein

Single synapse

Single cell

Cell assemblies

Network oscillations

Isolated cells

Cell cultures

Brain slices

Brain organoids

*In vivo*

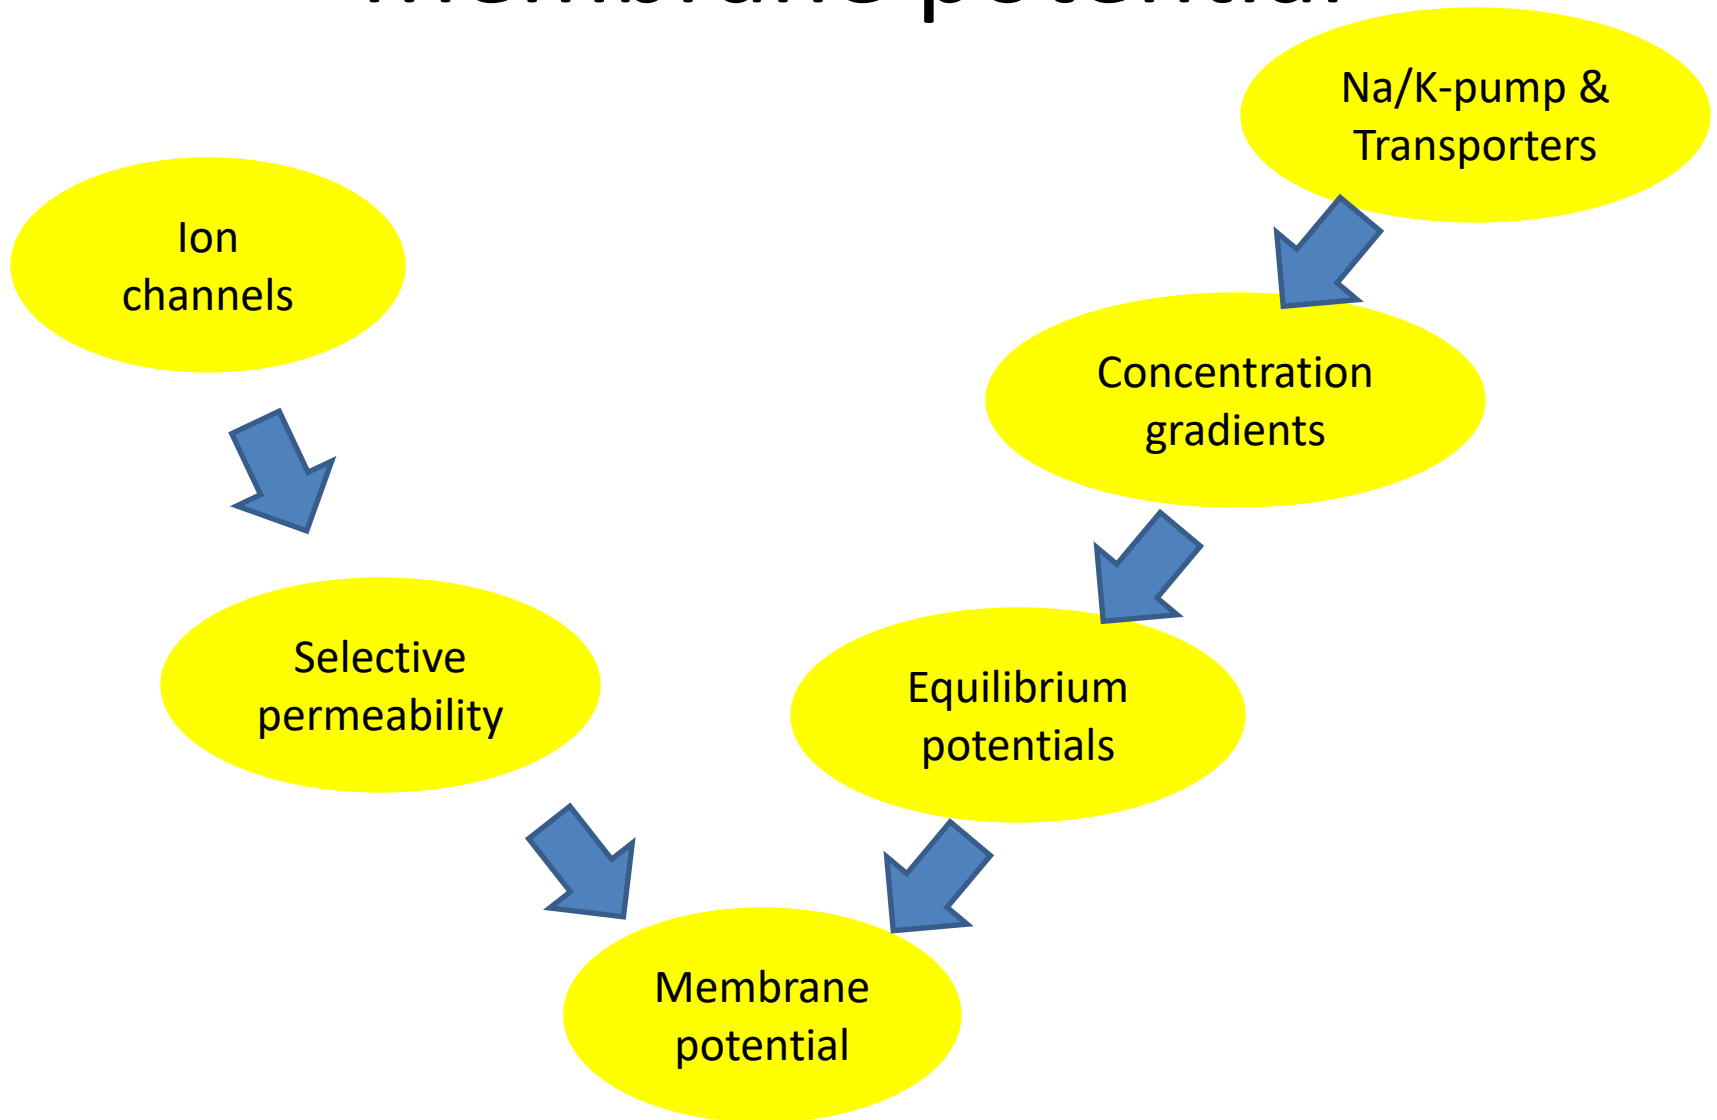

Patch-clamp recordings

Extracellular recordings

Optical recordings

Multielectrode array recordings

# Membrane potential

# Pumps, concentration differences and equilibrium potential

## Nernst equation

$$E_{\text{ion}} = 2.303 (RT/zF) \log([j_{\text{ion}}]_o/[j_{\text{ion}}]_i)$$

$$E_{\text{ion}} = 61.54 \log([j_{\text{ion}}]_o/[j_{\text{ion}}]_i)$$

Ion concentrations in human cerebrospinal fluid and serum (in mM)

	Cerebrospinal fluid	Serum	Correlation
K <sup>+</sup>	2.9	4.2	No
Na <sup>+</sup>	147	140	Yes
Cl <sup>-</sup>	125	100	No
Ca <sup>2+</sup> Total	1.2	2.4	Yes
Ca <sup>2+</sup> Free	1.0	1.2	
Mg <sup>2+</sup> Total	1.2	0.8	No
Mg <sup>2+</sup> Free	1.0	0.5

# Ion channels

		Gating							
Selectivity		Voltage	Ligand	Ca <sup>2+</sup> , cAMP, cGMP	Temp	Mech	H <sup>+</sup>	“leak”	
	Na								
	K								
	N/K								
	N/K/Ca								
	Ca <sup>2+</sup>								
	Cl/HCO <sub>3</sub>								

# Leak channels

The resting permeability for K<sup>+</sup> is much higher than for Na<sup>+</sup>, but the driving force (at resting membrane potential) is much higher for Na<sup>+</sup> than for K<sup>+</sup>. The resultant currents for K<sup>+</sup> and Na<sup>+</sup> are therefore equal

# Membrane potential

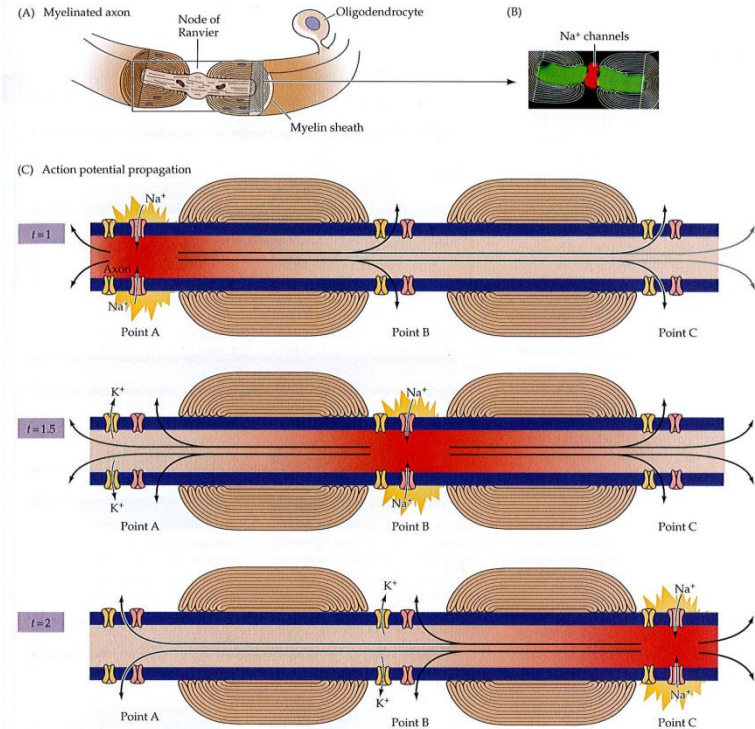

The Goldman equation  $V_m = 61.54 \text{ mV} \log \frac{P_K [K^+]_u + P_{Na} [Na^+]_u}{P_K [K^+]_i + P_{Na} [Na^+]_i}$

# Action potential – “all-or-none”

# Propagation of the action potential

Myelin  
Diameter  
Temperatur

	Muscle nerve	Cutaneous nerve	Fiber diameter ( $\mu\text{m}$ )	Conduction velocity (ms)
Myelinated				
Large	I	A-C	13-20	80-120
Small	II	A $\beta$	6-12	35-75
Smallest	III	A $\delta$	1-5	5-30
Unmyelinated	IV	C	0.2-1.5	0.5-2

# Extracellular recording of action potentials

# Refractory period following the action potential

**Absolute refractory period** = Voltage-gated Na<sup>+</sup>-channels are inactivated, making a new action potential impossible.

**Relative refractory period** = Voltage-gated Na<sup>+</sup>-channels de-inactivates during this period and the membrane potential is hyperpolarized. A stronger than normal depol is required to evoke an action potential.

# Optical recording of the action potential

Cortical pyramidal cell:  
ca. 30000 Glutamate synapses (90%)  
ca. 2000 GABA synapses (10%)

# Presynaptic release of transmitter vesicle

(C)

SNARE-mediated exocytosis

# Glutamate uptake in astrocytes

# Synapses are usually small and unreliable, but many (and plastic)

3 quantal parameters determine the signalling strength of a synaptic connection

$$\text{Synaptic strength} = n \times p \times q$$

$n$  = no. of release sites

$p$  = release probability

The probability that an action potential will cause the release of one vesicle

$q$  = quantal size

The magnitude of the postsynaptic response to one vesicle

1 μm

# The Glutamate synapse

## 1. The AMPA receptor channel:

- opened by glutamate
- permeates  $\text{Na}^+$  and  $\text{K}^+$
- gives rise to a brief (ca. 10 ms) EPSP

## 2. The NMDA receptor channel:

- opened by glutamate (and Gly/D-Ser) + depol
- permeates  $\text{Na}^+$ ,  $\text{K}^+$  and  $\text{Ca}^{2+}$
- gives rise to a brief long-lasting (ca. 100 ms) EPSP
- is necessary for the induction of synaptic plasticity; Long-term potentiation (LTP) och long-term depression (LTD).

- ## 3. Metabotropic glutamate receptors (mGluRs) are G-protein coupled receptors that, for example, can give rise to $\text{Ca}^{2+}$ release from ER and facilitate synaptic plasticity.

Type A GABA (γ-aminobutyric acid) receptors (GABA<sub>A</sub> receptors) mediate most fast inhibitory signalling in the brain and are targets for drugs that treat epilepsy, anxiety, depression and insomnia and for anaesthetics<sup>1,2</sup>. These receptors comprise a complex array of 19 related subunits, which form pentameric ligand-gated ion channels. The composition and structure of native GABA<sub>A</sub> receptors in the human brain have been inferred from subunit localization in tissue<sup>3,4</sup>, functional measurements and structural analysis from recombinant expression<sup>5–7</sup> and in mice<sup>8</sup>. However, the arrangements of subunits that co-assemble physiologically in native human GABA<sub>A</sub> receptors remain unknown. Here we isolated α1 subunit-containing GABA<sub>A</sub> receptors from human patients with epilepsy. Using cryo-electron microscopy, we defined a set of 12 native subunit assemblies and their 3D structures. We address inconsistencies between previous native and recombinant approaches, and reveal details of previously undefined subunit interfaces. Drug-like densities in a subset of these interfaces led us to uncover unexpected activity on the GABA<sub>A</sub> receptor of antiepileptic drugs and resulted in localization of one of these drugs to the benzodiazepine-binding site. Proteomics and further structural analysis suggest interactions with the auxiliary subunits neuroligin 2 and GRLH4, which localize and modulate GABA<sub>A</sub> receptors at inhibitory synapses. This work provides a structural foundation for understanding GABA<sub>A</sub> receptor signalling and targeted pharmacology in the human brain.
